

Analysis of pollution in the neighborhood of opencast coal mine

Eliška Cézová

Department of Designing and Machine Components
Faculty of Mechanical Engineering
Czech Technical University in Prague

Introduction

Data available for the analysis

Original data

Partially filtered data

Fully filtered data

Dynamics of wind flow over the opencast mine

Conclusions

This presentation is a part of the project TA01020428:
“Investigation of possibilities of employment of physical and mathematical models in solution of dustiness in real conditions of being terrain”

A joint project of:

- **Ecoprogress a.s.**
- **Institute of Thermomechanics AS CR**
- **Czech Technical University in Prague**

Project was supported by the **Technology Agency of the Czech Republic**

The aim of the project was to develop tools and methods allowing accurately predict and efficiently reduce the airborne dust pollution. The focus is on environmental applications including large-scale mining and industrial activities.

The project had three main parts:

1. In-situ investigation and implementation (Ecoprogress a.s.)
2. Wind-tunnel measurements (IT AS CR)
3. Mathematical modelling and numerical simulation (CTU Prague)

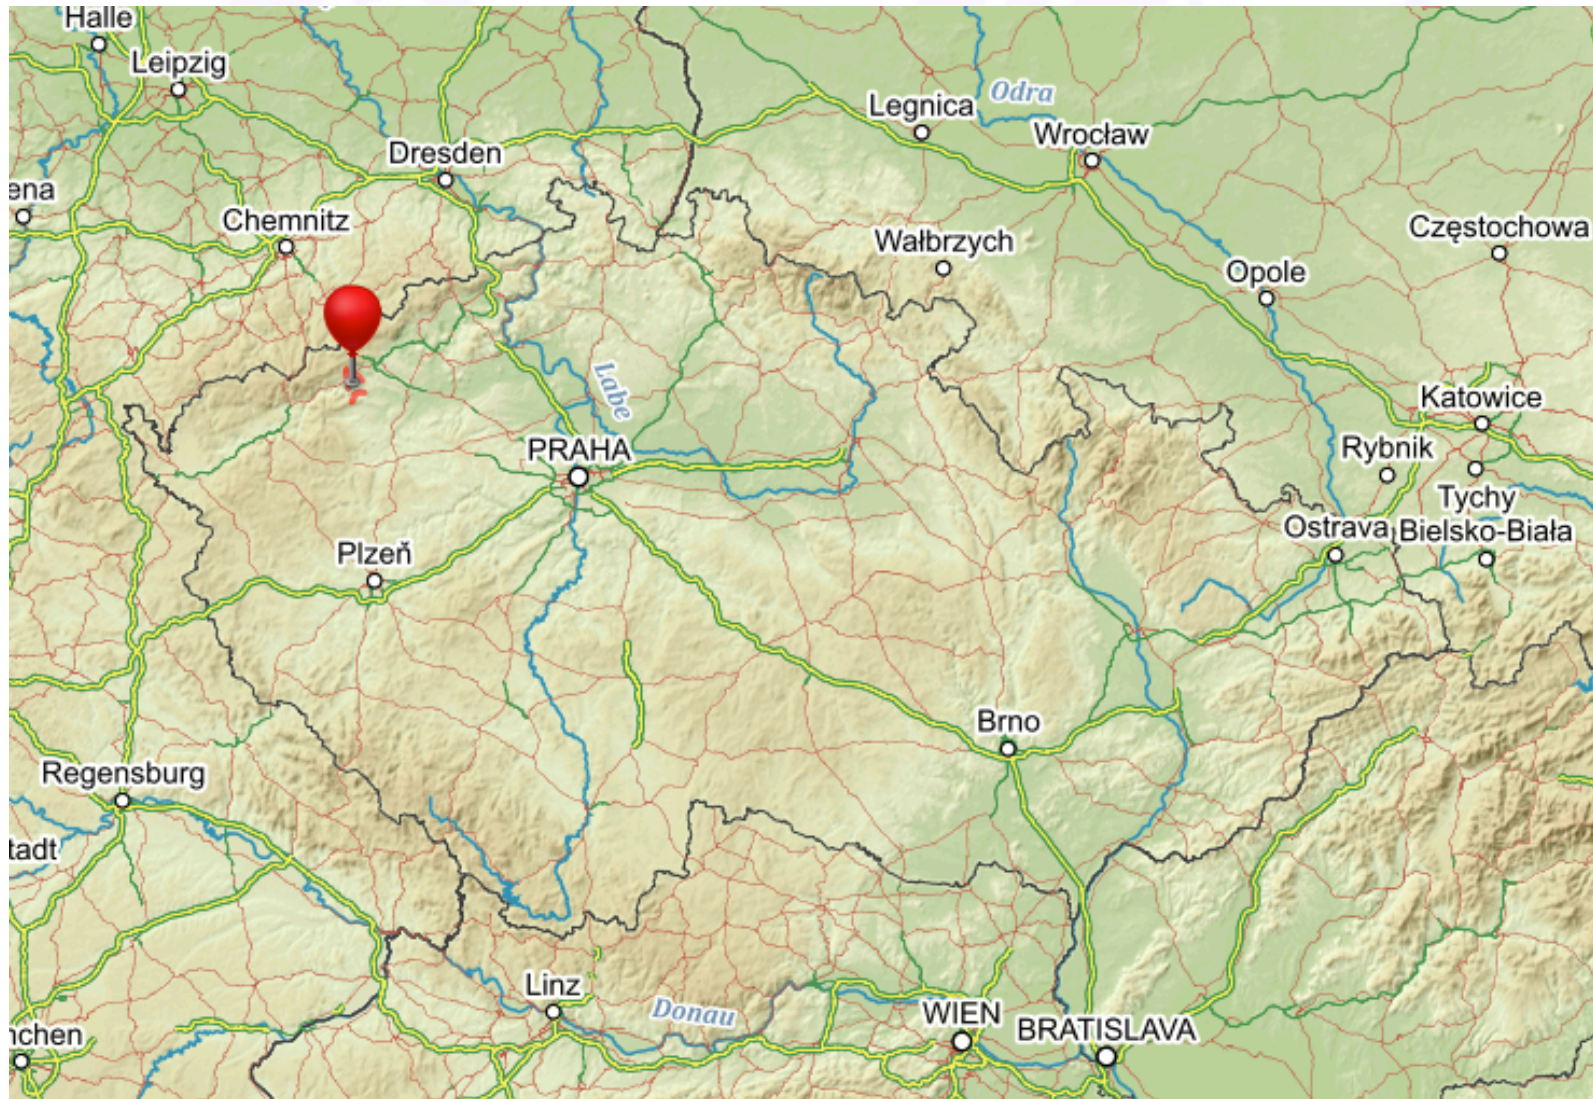

The investigation of flow and pollution dispersion in the proximity of an opencast coal mine was chosen as a test case for the tools and methods developed within this project.

As a part of the real terrain in-situ observations a long term meteorological data measurements were performed.

A huge amount of data was collected and had to be processed and evaluated.

The first aim of the data analysis was to identify and to fix some of the major problems contained in collect meteorological data.

- * Data were "continuously" collected throughout the year 2012-2014 and recorded at minute frequency.
- * The whole data set contained 3 153 600 observations/year.
- * Many records found in these data sets were either invalid or exceptional e.g. extremely distant in some sense.

Prototypes of the "exceptional" data:

- * were localized in one or several neighbouring points
- * quite large time intervals were affected

Such singular values were filtered out and replaced by NaN symbols, i.e. treated as undefined in further analysis.

In some case, where only single values or short time intervals were affected, the missing data can be substituted using interpolation from the neighboring unaffected values.

Measured variables:

- * wind velocity in $[m/s]$,
- * wind direction as azimuth angle in degrees $[^\circ]$,
- * pressure $[MPa]$,
- * air temperature in $[^\circ C]$,
- * atmospheric relative humidity in $[\%]$,
- * solar radiation intensity in $[W/m^2]$,
- * **atmospheric aerosol concentration PM_{10} $[\mu g/m^{-3}]$.**

Date Time	PM10	Velocity	Direction	Temp.	Humidity	Solar rad.	Pressure

Examples of extremal values from stations 231 - 236

The invalid data records had to be filtered out from the data files and excluded from further processing.

The following data were assumed to be invalid and have been excluded from the original raw data sets:

- * Negative concentrations of aerosol concentrations $PM_{10}[\mu\text{g}/\text{m}^3]$.

 - In total 5 822 data records were excluded.

- * Negative values of wind speed $[\text{m}/\text{s}]$.

 - In total 63 937 records were excluded.

- * Negative values of solar radiation intensity $[\text{W}/\text{m}^2]$.

 - In total 308 305 records were excluded.

- * Extremely low barometric pressure values $< 940 \text{ hPa}$.

 - In total 65 records were excluded.

Conclusions

Despite of the above mentioned problems it can be concluded that the data, provided some a-priori filtering and pre-processing will be applied, can be used for the analysis of pollution dispersion conditions and other meteorological phenomena in the area of the opencast coal mine.

- * This preliminary data exploration discovered many problems in acquisition and storage of the data.
- * These problems are mainly of technical origin and have to be resolved before undertaking any further steps in analysis of the data.
